# Extending municipal water demand forecasting capacities

Steven Renzetti, Diane P. Dupont and James Price Brock University

# 1. Background

- 2008 AWWA survey: most North American water utilities forecast water demands by multiplying future population estimates by historical per capita water use
- Gleick (2000): almost all of the projections based on fixed-coefficient models of wateruse significantly overstated actual water.

# 1. Background

- One solution: Large variety of forecasting tools and methods are available – rely on sophisticated numerical and statistical methods and large amounts of data
- Problem: many water suppliers lack capacity (data, HR, etc.) and knowledge of user characteristics to carry out simulations & forecasts

# Objectives

Develop a user-friendly, spreadsheet-based demand forecasting and simulation tool that:

 provides water utilities with the capacity to project medium-term demands
 accounts for planned or expected changes in important demand drivers (e.g. price)
 supports community engagement

# The simulation program

Key features:

- Residential water demands
- User inputs demand driver growth rates
- Price changes can be simple or complex; onetime or on-going
- Price and income elasticities can be input or chosen from default values

Here are some screen captures:

#### Introduction

### Example

- ▶ Pop ↑ (5% p.a.), income ↑ (2% p.a.)
- Modest DSM measure in place
- Price 1 (5% p.a.) for 20 years

Case 1: price elasticity of demand =-0.5
Case 2: price elasticity of demand =0.0

#### Case 1: no price response

#### Case 2: price responsive

2013 2010

# Benefits to water agencies

- (1) produce more accurate water demand projections
- assess potential impacts of pricing and other policy measures,
- (3) integrate capital investment planning and demand-side management
- (4) engage stakeholders

### Next steps

 Add more examples to user manual (apparently "price elasticity of demand" isn't as obvious as we thought...)

Add ICI sector's demands
