

# Integrated assessment of multiple characteristics for extreme climatic events under climate change

Dr. Qingsong Wu  
Prof. & Dr. Qiting Zuo  
Zhengzhou University

# Content

- Motivation
- Material and methods
- Results and discussion
- Innovation and limitation

- In the context of global warming, regional climate change has become one of the top concerns of human society due to its **complex uncertainties** and the **severity of disasters**.
- The **Sixth Assessment Report** of the United Nations Intergovernmental Panel on Climate Change stated that climate change would **continue to intensify** in all regions of the world in the coming decades, and that climate disasters will become **more frequent and severe**. (IPCC Core Writing Team, 2021)

**Human activities**

Cause

**Global warming**

Lead

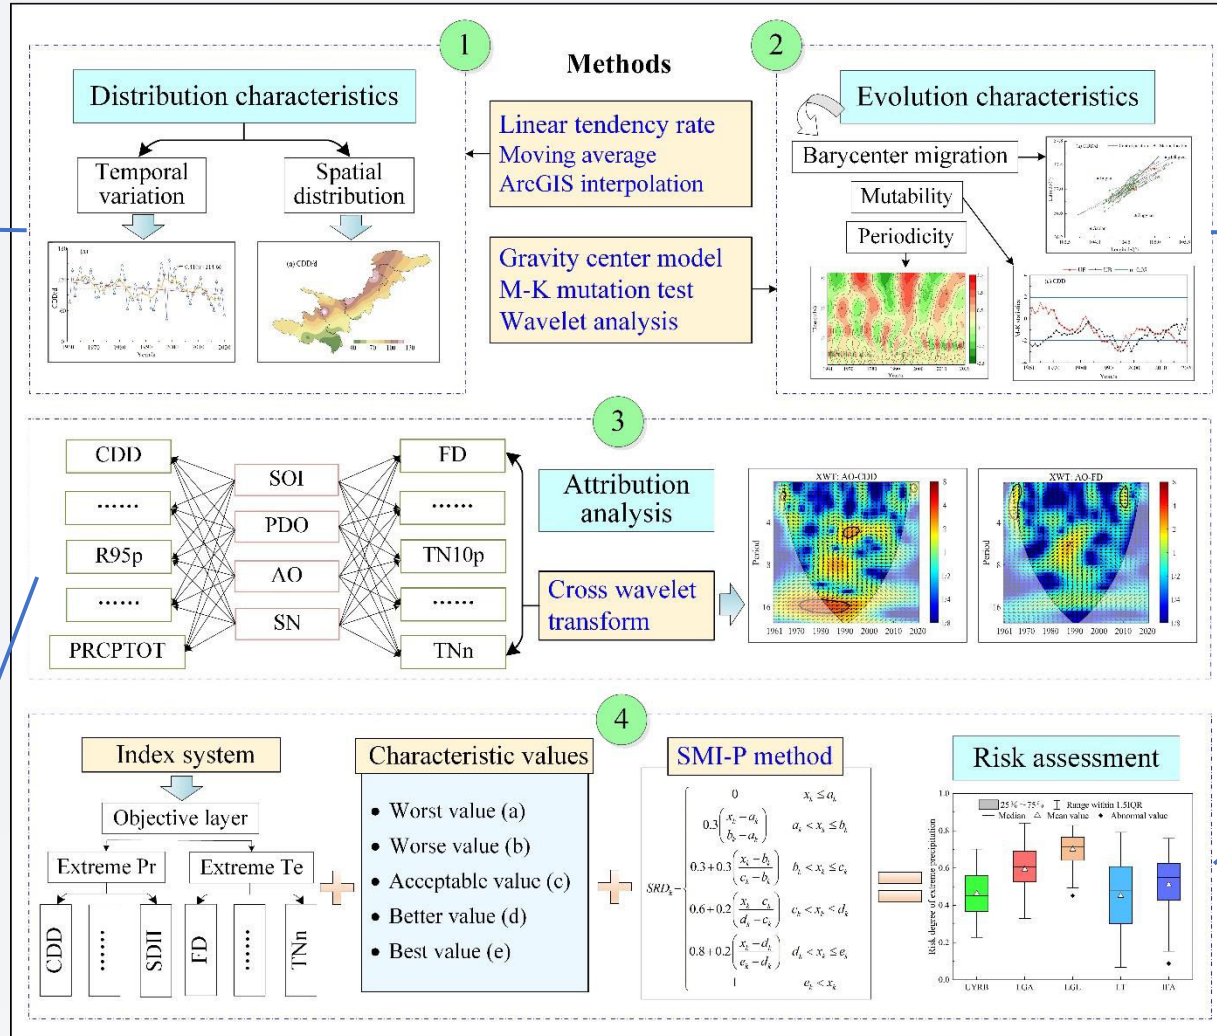

**Extreme climatic event**

**Regional dry and wet change**

It is of great significance to study the **occurrence and development** of extreme climates from multiple **scales, dimensions, and perspectives**.

## ➤ Concrete content

Temporal variation and spatial distribution of extreme climate events, which is a direct analysis of extreme climate conditions.

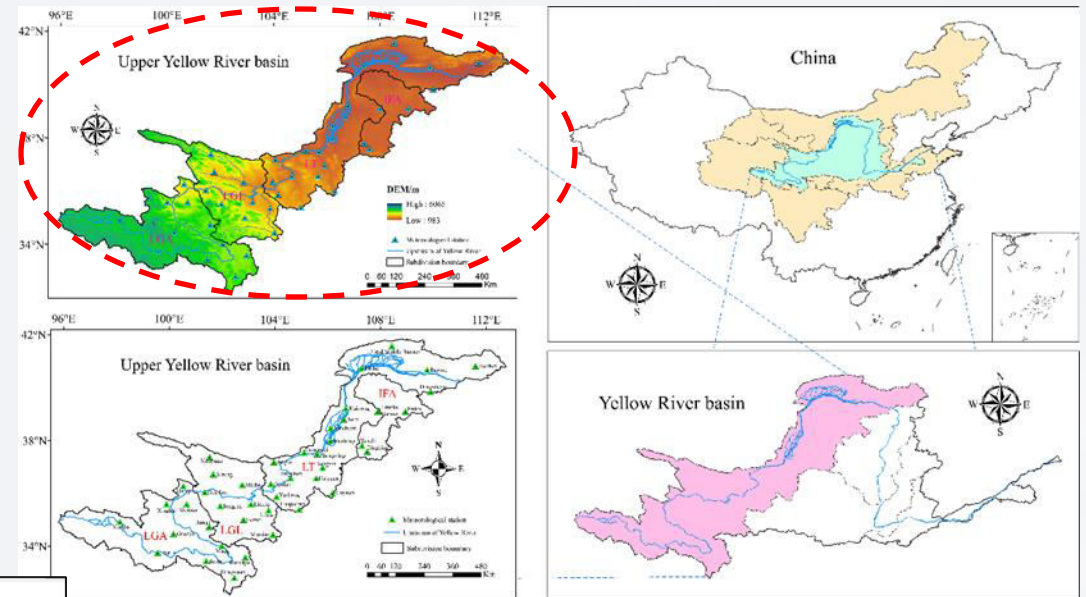

To explore the tele-connection between atmospheric circulation, solar activity and extreme climate change, and to identify the main drivers.

Mutability and periodicity of extreme climate events, a reanalysis of extreme climate conditions.

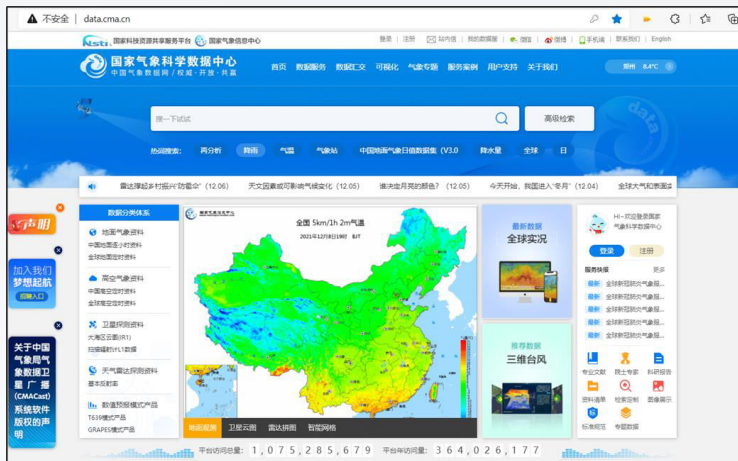

Combining two aspects of extreme Pr and Te, to assess the risk degree and level of climatic extremes.

## ➤ Material

- The upper reaches of the Yellow River are about **3,472 kilometers** long, the Upper Yellow River basin (UYRB) covers an area of **417.4 thousand km<sup>2</sup>**.
- Four secondary watersheds: Longyang Gorge above (**LGA**), Longyang Gorge to Lanzhou (**LGL**), Lanzhou to Toudaoguai (**LT**) and Inner flow area (**IFA**).

Study period: **1961-2020**

- Daily precipitation and temperature data are derived from **China Surface Climatological Dataset** of the China Meteorological Data Network.
- Atmospheric circulation factor and sunspot data from the **National Oceanic and Atmospheric Administration (NOAA)**.

[https://psl.noaa.gov/gcos\\_wgsp/Timeseries/](https://psl.noaa.gov/gcos_wgsp/Timeseries/)

## ➤ Methods

### The first step: Selection and calculation of extreme climate indices

7 extreme Pr indices and 9 extreme Te indices were selected from perspectives of **absolute threshold**, **relative threshold** and **extreme value**; the calculations were made using the **RclimDex software**.

### The second step: The application of various methods

	Precipitation (Pr)	Temperature (Te)
Absolute threshold index	<b>Consecutive dry days (CDD, d)</b> Maximum number of consecutive days with $Pr < 1\text{mm}$ <b>Consecutive wet days (CWD, d)</b> Maximum number of consecutive days with $Pr \geq 1\text{mm}$ <b>Heavy precipitation days (R10, d)</b> Annual count of days when $Pr \geq 10\text{mm}$	<b>Frost days (FD, d)</b> Annual count when $TN$ (daily minimum) $< 0^\circ\text{C}$ <b>Ice days (ID, d)</b> Annual count when $TX$ (daily maximum) $< 0^\circ\text{C}$ <b>Summer days (SU25, d)</b> Annual count when $TX > 25^\circ\text{C}$
Relative threshold index	<b>Very wet days (R95p, mm)</b> Annual total Pr when daily Pr $\geq$ 95th percentile	<b>Cool days (TX10p, d)</b> Number of days when $TX <$ 10th percentile <b>Cool nights (TN10p, d)</b> Number of days when $TN <$ 10th percentile <b>Warm days (TX90p, d)</b> Number of days when $TX >$ 90th percentile <b>Warm nights (TN90p, d)</b> Number of days when $TN >$ 90th percentile
Extreme value index	<b>Max 5-day Pr amount (RX5, mm)</b> Monthly maximum consecutive 5-day Pr <b>Simple daily intensity index (SDII, mm/d)</b> Annual total Pr divided by the number of wet days ( $Pr \geq 1\text{mm}$ ) <b>Annual total wet day Pr (PRCPTOT, mm)</b> Annual total Pr in wet days ( $Pr \geq 1\text{mm}$ )	<b>Max Tmax (TXx, °C)</b> Yearly maximum value of daily maximum Te <b>Min Tmin (TNn, °C)</b> Yearly minimum value of daily minimum Te

### Content

1. Spatial and temporal distribution features

2. Evolution characteristics in time history

3. Attribution analysis of extreme climatic events

4. Assessment of the risk degree and level

### Methods

a) Climate tendency rate; b) Moving average method; c) Kriging interpolation method

a) Mann-Kendall mutation test (**Mutability**); b) wavelet analysis (**Periodicity**)

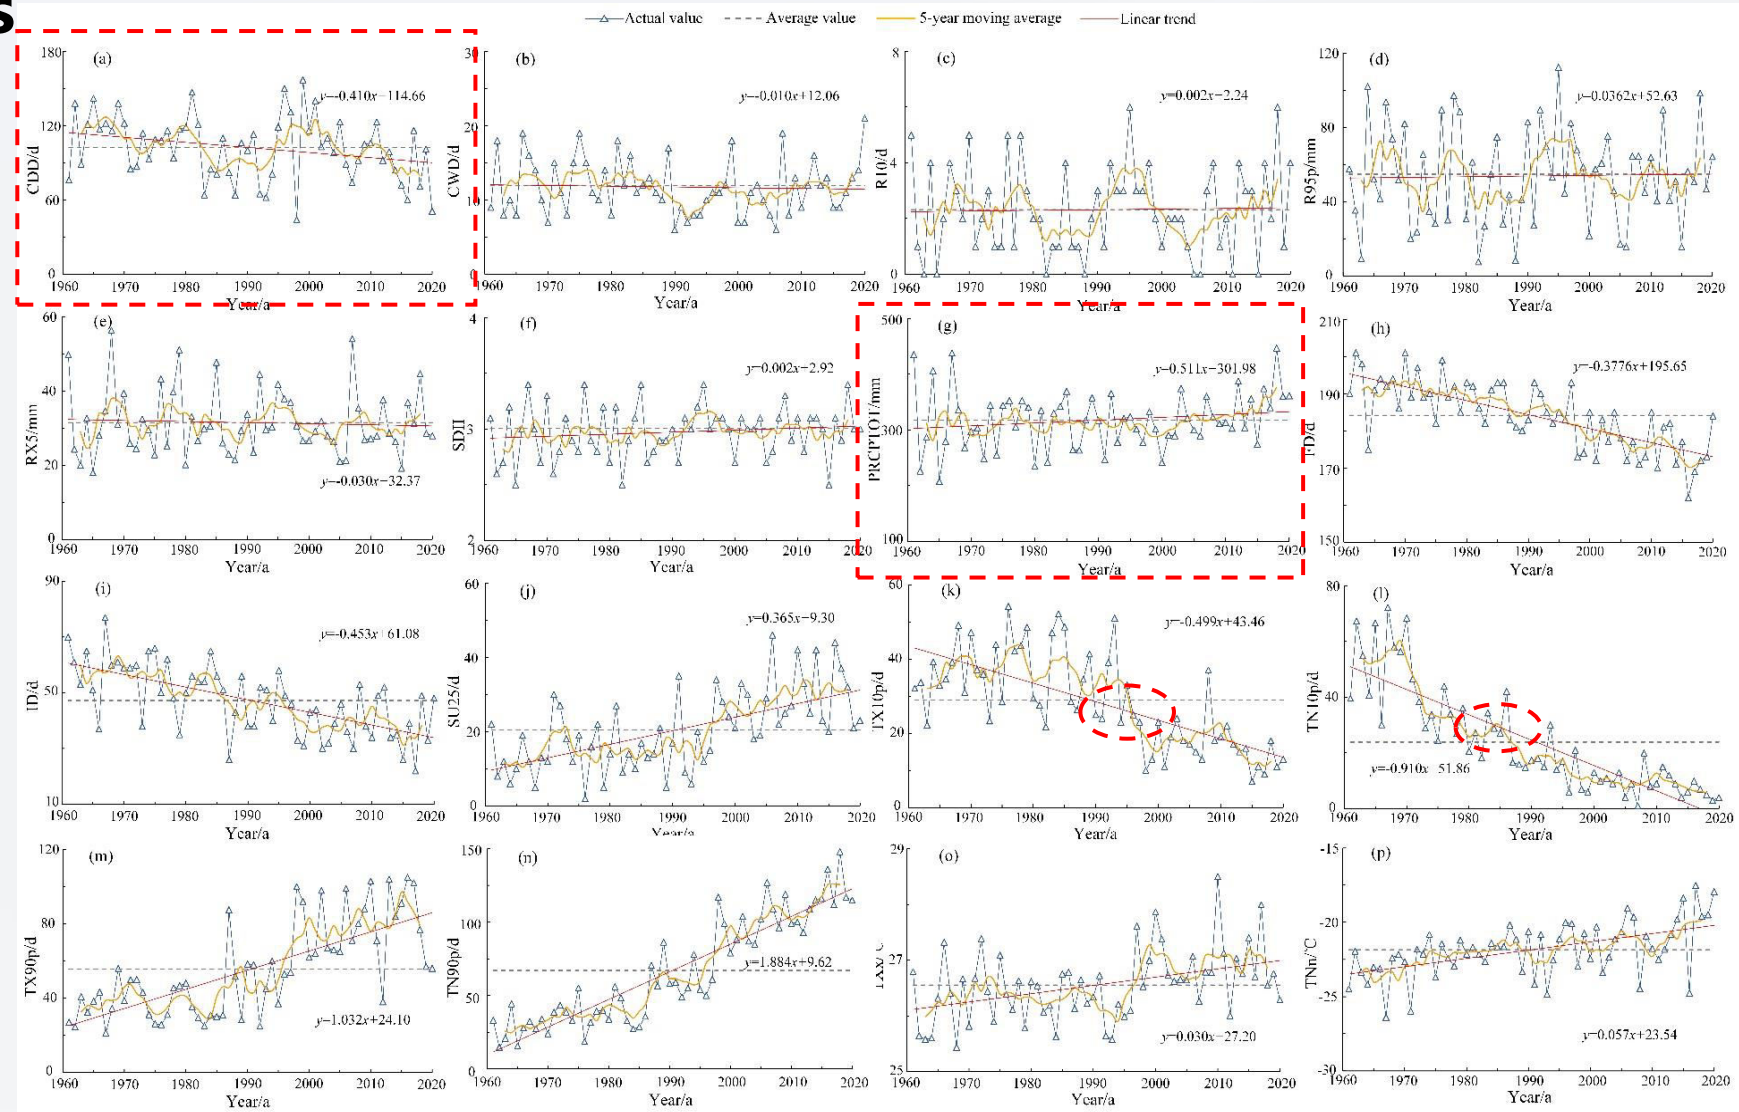

Cross wavelet transform (Achieved by *MATLAB*, <http://grinsted.github.io/wavelet-coherence/>)

Single index quantification and Multiple index synthesis and Poly-criteria integration (**Propose**)

## ➤ Distribution features

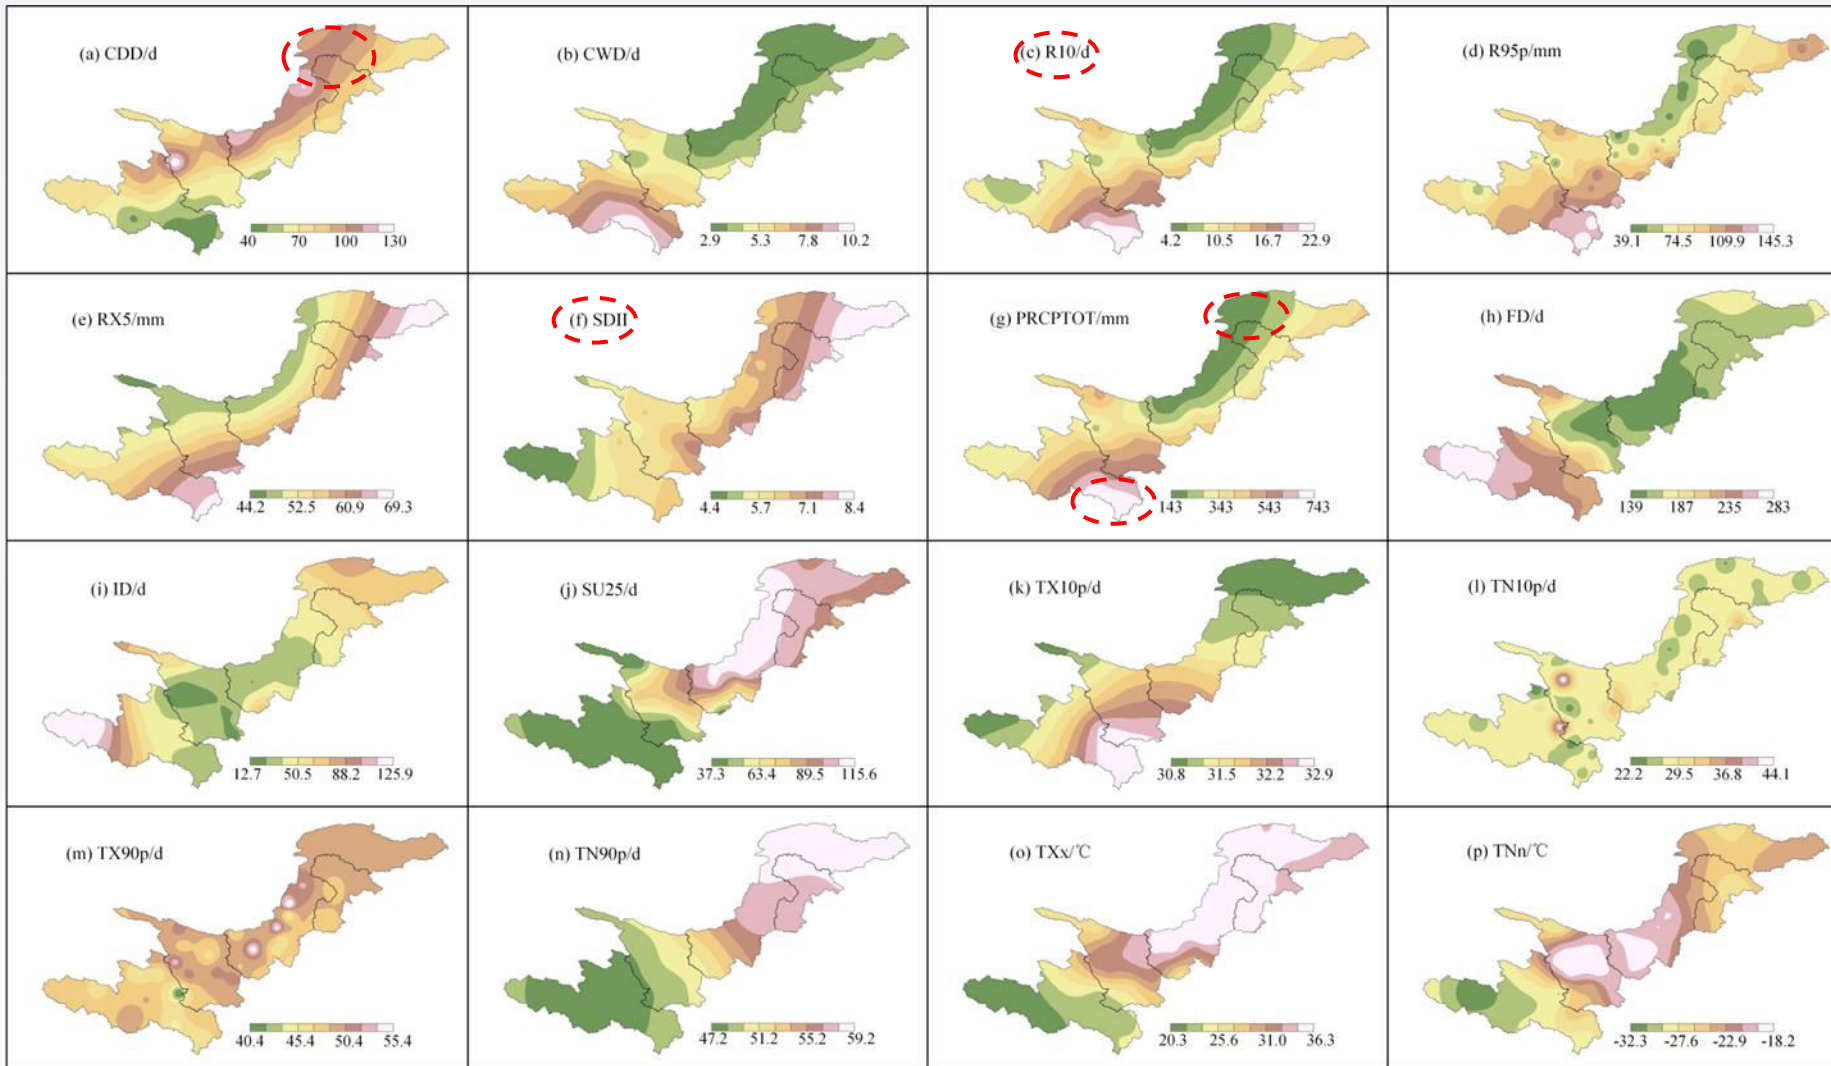

### 1. Temporal variation

- The interannual variation of consecutive dry days (CDD) and annual Pr (PRCPTOT) is evident, while the other indices show only a slight trend of variation. The **concentration and influence** of Pr is increasing.
- The trend of extreme Te index is **more significant** than that of extreme Pr index. The **intensity and frequency** of extreme high Te events have increased significantly.

## 2. Spatial distribution

Showing the intensity of extreme weather in different regions

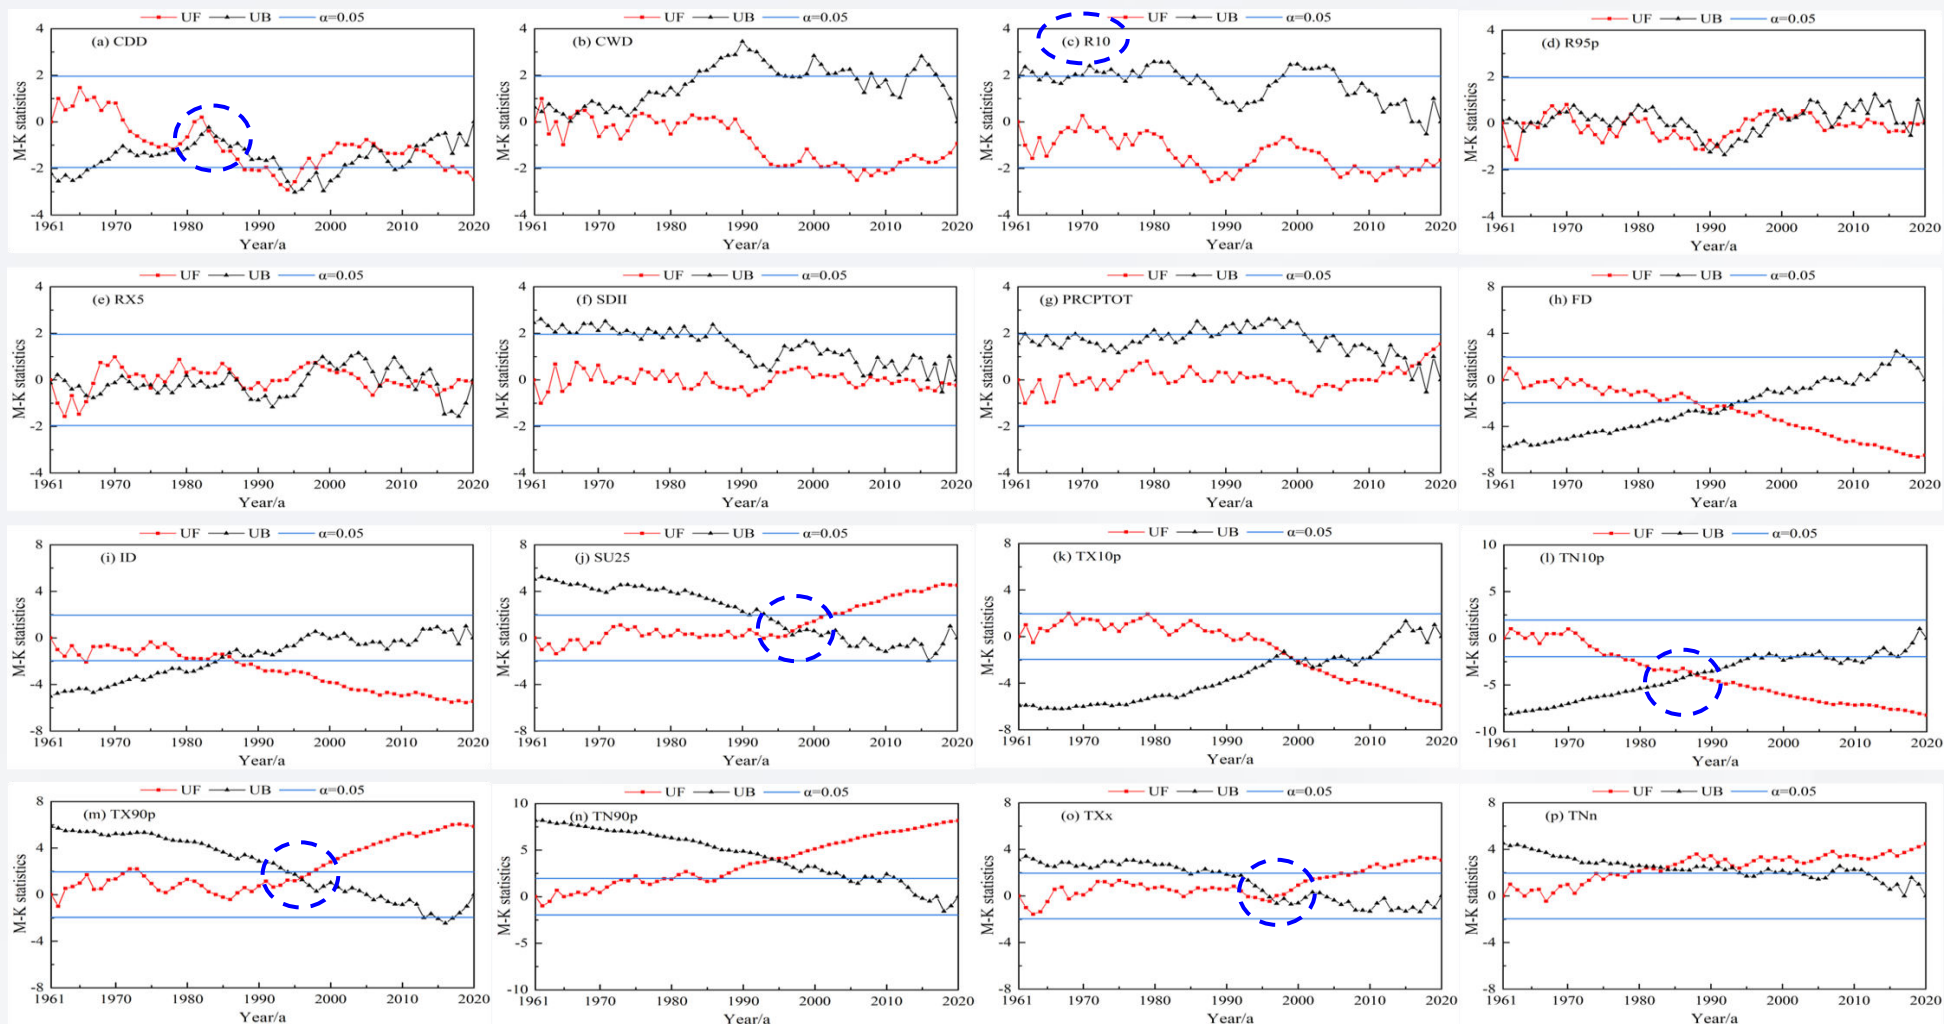

- The southeast of the basin is **wetter than** the northwest, where the number of continuous dry days even reaches 100-130.
- The number of days with heavy Pr is lower, but the intensity of Pr is higher in the eastern region, which is **more prone to** extreme Pr disasters.
- The spatial distribution of extreme Te events is **quite different** due to the apparent spatial differences in the topography and the intensity of human activity.

## ➤ Evolution features

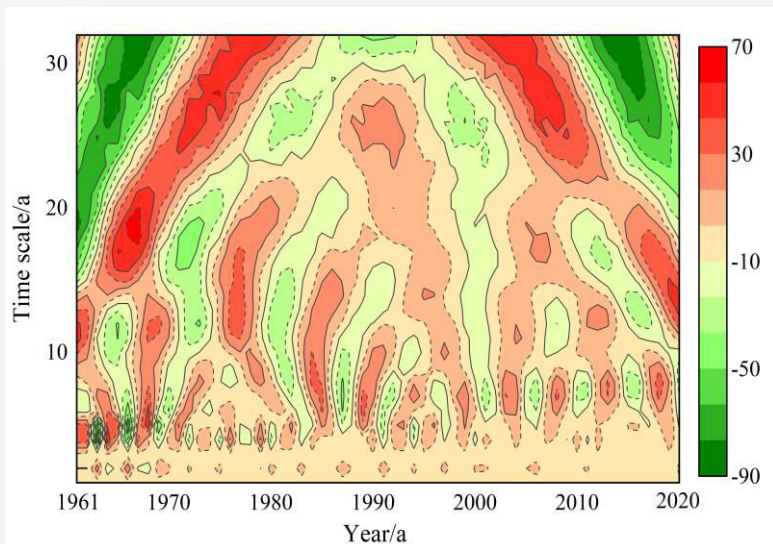

• In general, except for the heavy Pr days (R10) index, the UF and UB curves of all indices have **at least one** intersection.

### 1. Mutability test

- According to the number of intersections, it can be classified into **three types**: zero, one, and multiple intersections.
- The mutation features of the extreme Pr indices are **more complicated** than those of the extreme Te indices.
- The years of the index's abrupt changes vary widely, but most occurred in the **1980s and 1990s**.

## 2. Periodic analysis

Example: PRCPTOT

First primary period

Second primary period

Third primary period

Fourth primary period

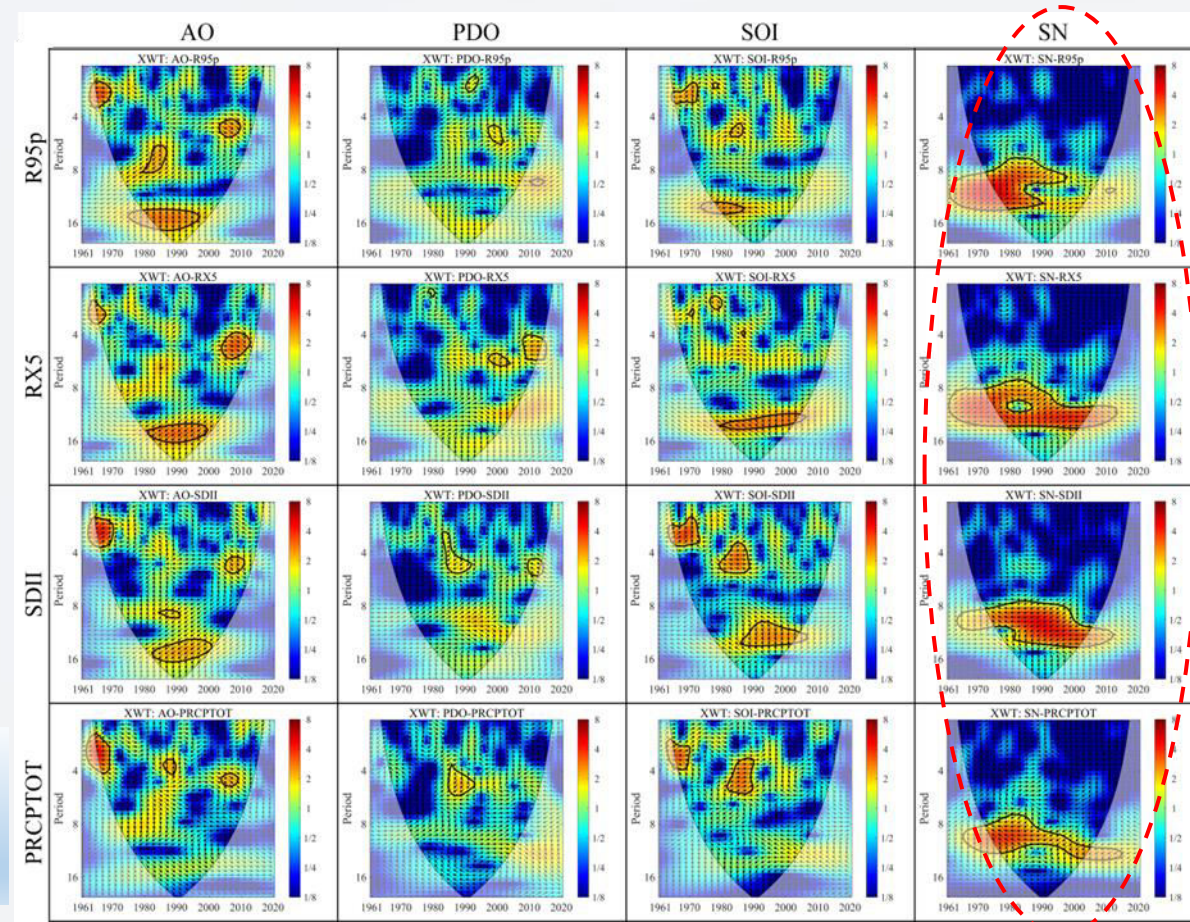

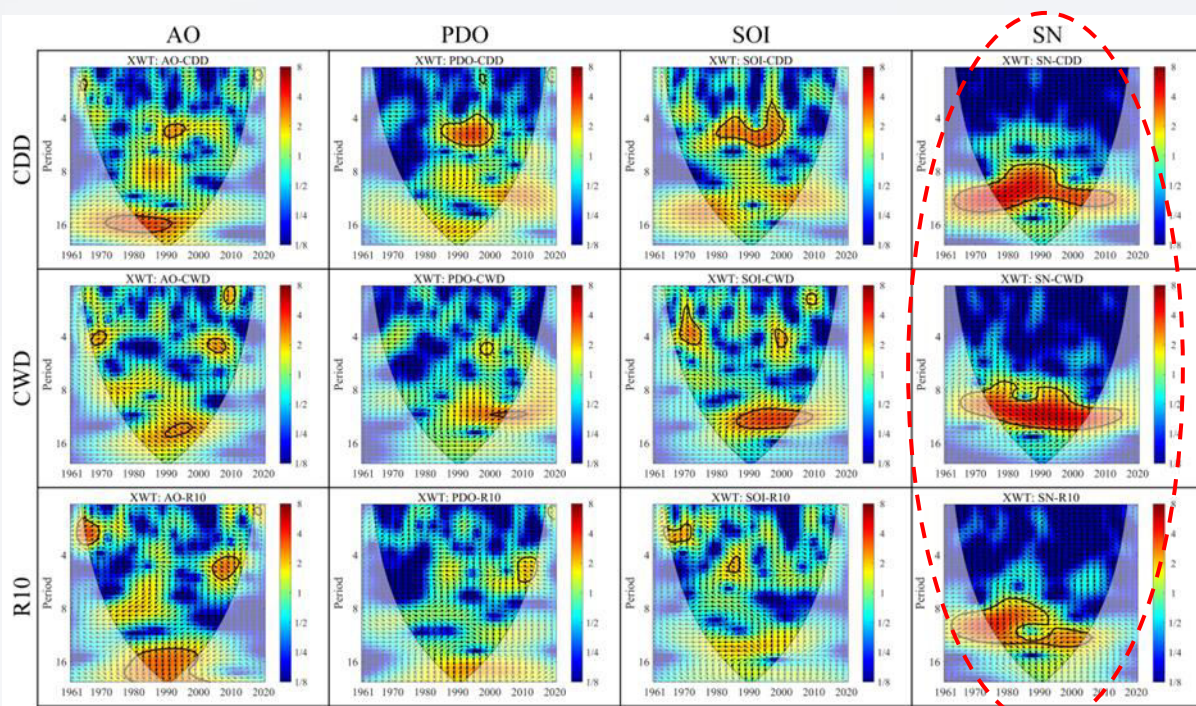

### Primary periods of extreme climate indices

Primary period	CDD	CWD	R10	R95p	RX5	SDII	PRCPTOT	FD
First	22	11	22	20	21	7	18	13
Second	7	16	8	13	12	5	5	4
Third	3	7	12	8	8		7	
Fourth		3	4	4	5		12	

Primary period	ID	SU25	TX10p	TN10p	TX90p	TN90p	TXx	TNn
First	27	8	28	22	14	14	10	28
Second	22	5	18	12	21	6	7	14
Third	12	14	20	4	6		4	6
Fourth	5	22	7					4

- The annual Pr has **four** primary periods (18a, 12a, 7a, 5a), but oscillations do not occur throughout the study period.
- With the exception of SDII, FD, and TN90p, almost all extreme climate indices have more than **two** primary periods, showing trends of **interannual and interdecadal oscillations**.
- Most indices generally have three types of periods, **large, medium, and small**, showing consistency, but their **time domain, frequency, and oscillation intensity** are quite different.

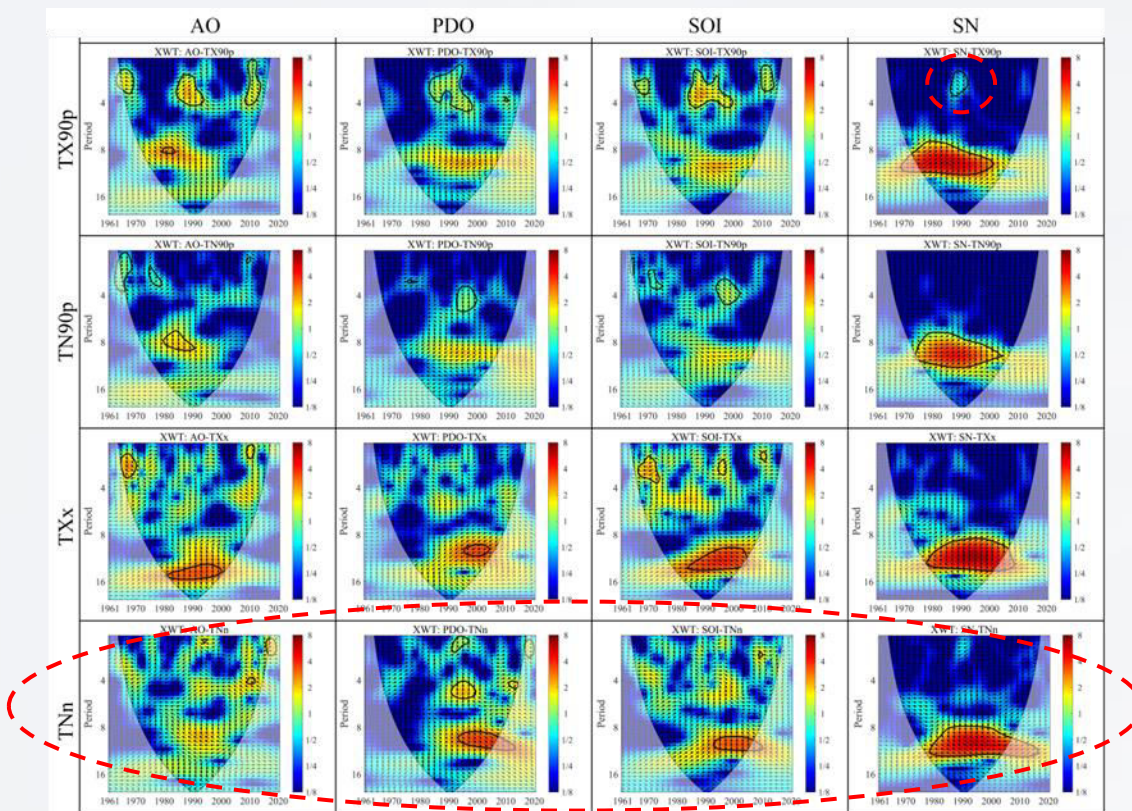

## ➤ Attribution analysis 1. Teleconnection between driving forces and Pr extremes

- The response relation between the selected driving force and the extreme Pr index **differs significantly** in terms of **index category**, **resonance intensity**, **time domain**, and **phase relation**.

- In terms of driving forces, almost all indices with AO and SOI have **larger resonance periods** and **intensities** than PDO, and exhibit features of **multiple time scales** and **long time domains**.
- There is a correlation between the SN and the extreme Pr index on scales **8-14a**, which is related to the mean period of solar activity at 11a.

## 2. Teleconnection between driving forces and Te extremes

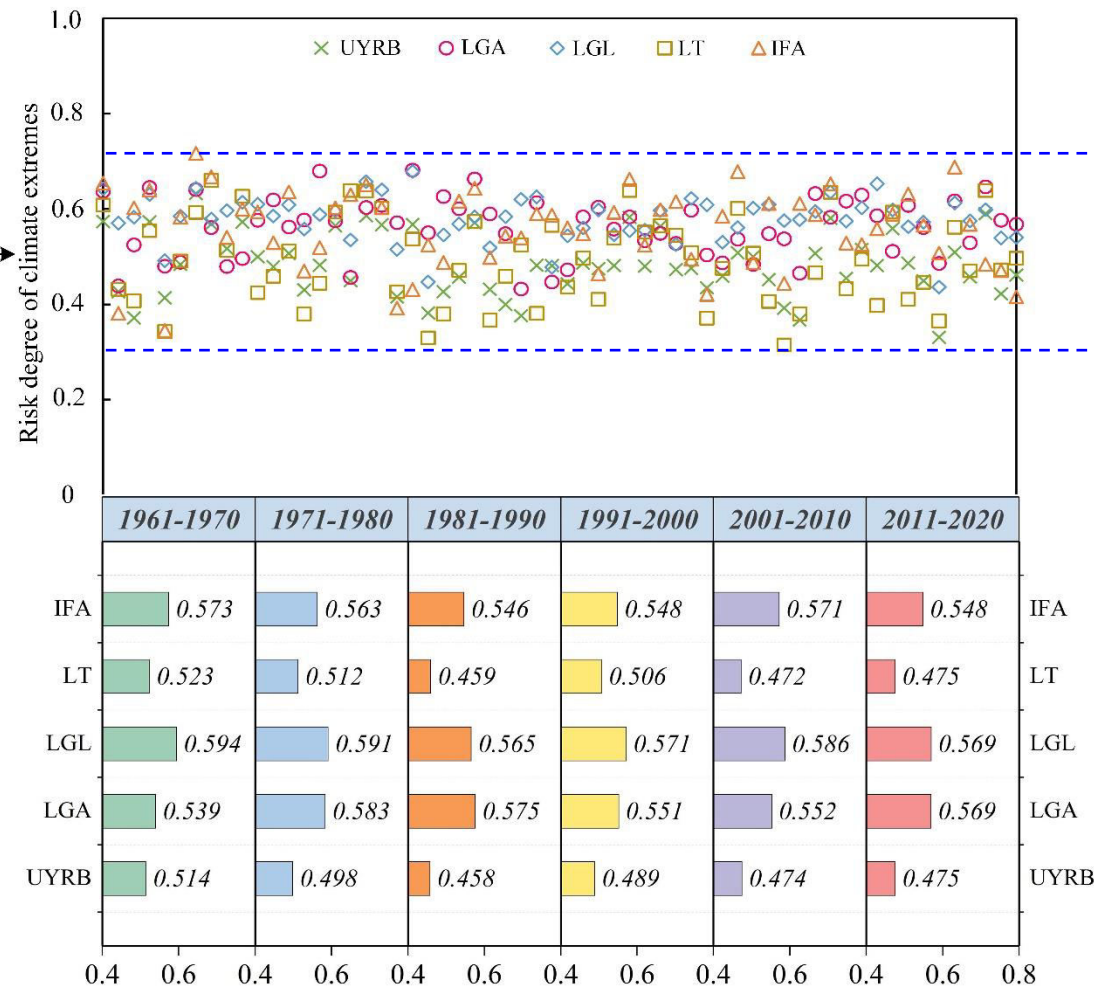

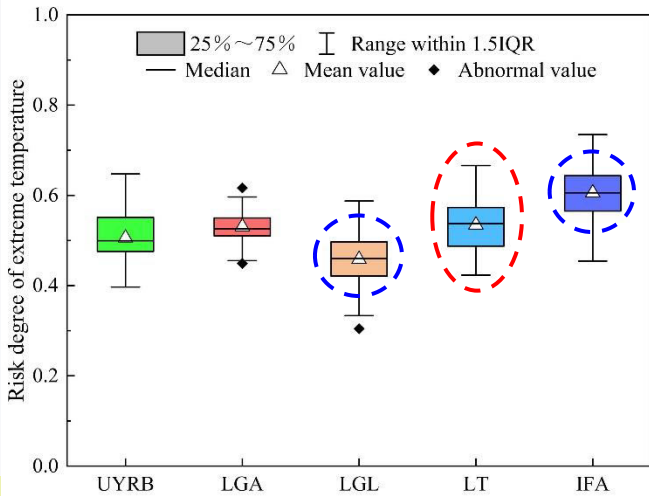

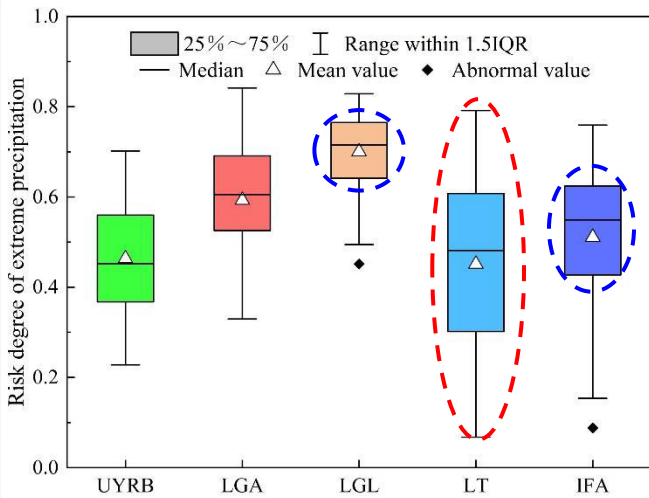

- Similar to the extreme Pr index, the correlation between AO and SOI is **stronger** than PDO for almost all extreme Te indices except for the minimum temperature (TNn).

- There is also a **significant correlation** between the SN and the most extreme Te indices at **large scale** period.
- The correlation between the extreme Te index and the selected driving force is **weaker** than that of the extreme Pr index, indicating that the Pr extremes is **more strongly and more complexly affected** by atmospheric circulation.

## ➤ Risk analysis

- The risk degree of extreme Pr and Te is **diverse** among subbasins. The overall **risk degree** of extreme Pr in the same region is **larger** than that of extreme Te, and its **variation range** is also **larger**, mainly due to the complex uncertainty of Pr.

The overall risk of extreme climate is in the range of **0.3 to 0.7**, with a **fluctuating trend** from 1961 to 2020.

- Regions with a **high** risk of extreme Pr may have a **lower** risk of extreme Te, while the situation is different for the **Inner flow area (IFA)**.
- The occurrence of extreme Pr and Te events is **not spatially and temporally synchronized**, so **copied strategies** should be formulated based on the actual situation.

## ➤ Innovation

- An **Distribution-Evolution-Attribution-Risk (DEAR) framework** was developed.
- A novel risk assessment idea for climatic extremes was **proposed** with the SMI-P method.
- The DEAR framework was **applied to** a real case of Upper Yellow River basin, China.
- Extreme climatic events were examined with multiple **scales, dimensions and aspects**.
- Findings can help clarify the **occurrence and development laws** of climate extremes.

## ➤ limitation

**1** The occurrence and variation of climatic extremes are influenced by **multiple factors**. An **all-sided attribution analysis** involving many factors should be carried out.

---

**2** The characteristic values applied in the risk assessment are determined by the **percentile of the data series**. **Universal standard** should be explored further.

---
